

Math Problem Set 1

Tim Munday

Section one answers

Ex 1.3

G1 - Since G1 only includes open sets, it is not closed under complements and finite unions (since the complements of open sets are necessarily closed), and so cannot be an algebra.

G2 - G2 is an algebra, but not a σ -algebra. It fulfils the two requirements of containing the empty set and being closed under complements and finite unions that are needed to be an algebra. However, since the unions are not countable G2 is not a σ -algebra.

G3 - G3 is a σ -algebra. It passes both requirements: containing the empty set and is closed under countable unions.

Ex 1.7

Part a

We know that both examples are σ -algebras. Both contain the empty set (by definition), and are closed under countable unions. Then since $P(X)$ is the largest set such that all members are in X , it must be the largest σ -algebra.

Part b

The first condition for a σ -algebra is that \emptyset is a member. The second condition is that a σ -algebra must be closed under complements. Thus if it contains \emptyset it must also contain X at a minimum. Therefore the smallest σ -algebra is $\{\emptyset, X\}$.

Ex 1.10

Condition 1

If \emptyset is in all S_α then it is also in the intersection of the S_α , i.e. it is contained within $\bigcap_\alpha S_\alpha$.

Condition 2

Suppose $A \in \bigcap_\alpha S_\alpha$ then clearly A is in all S_α . Since all the S_α are closed under complements (as they are σ -algebras), then A^c is in all S_α and so is also in the intersection of the S_α . Therefore the intersection of the S_α is closed under complements, so the second condition is satisfied.

Ex 1.17

Prove monotonicity

We want to prove μ is monotone. i.e. if $A, B \in S, A \subset B$ then $\mu(A) \leq \mu(B)$

Let us define $Y = B \cap A^c$ We know that $Y \in S$ $\mu(Y \cap A) = \mu(A) + \mu(Y)$ as A and Y are disjoint $\mu(B) = \mu(A \cap B) + \mu(Y) = \mu(A) + \mu(Y)$ Since $\mu(Y) \geq 0$ Then $\mu(A) \leq \mu(B)$ So the proposition is proved

Prove countable subadditivity

Define a sequence of new sets: $B_1 = A_1, B_2 = A_2 - A_1, B_3 = A_3 - (A_1 \cup A_2)$ and so on and so forth. Then we notice that $\bigcup_n A_n = \bigcup_n B_n$ We have already proved monotonicity, therefore we know that $\mu(B_n) \leq \mu(A_n)$ for all n . Summing over n we get the result that $\mu(\bigcup_n A_n) \leq \sum_n \mu(A_n)$

Ex 1.18

There are two conditions for a measure, that it assigns zero to the empty set, and that the measure of the union of a collection of sets is equal to the sum of the measures of those sets, if the sets are disjoint.

Condition 1

$\lambda(\emptyset) = \mu(\emptyset \cap B) = \mu(\emptyset) = 0$

Condition 2

$\mu(\cup_i^\infty A_i) = \mu(\cup_i^\infty A_i \cap B)$ If the A 's are disjoint, then so are their intersections with B . So defining $Y_i = A_i \cap B$ we can write: $\mu(\cup_i^\infty) = \Sigma \mu(Y_i) = \Sigma \mu(A_i \cap B)$

Ex 1.20

We realise that because we have a decreasing sequence of sets, $A_1 - A_n$ gets larger as n grows.

We can then use the result for increasing sets that is in the notes to construct the proof for decreasing sets.

$$\mu(\cap_{i=1}^\infty A_i) = \mu[A_1 - \cup_{i=1}^\infty (A_1 - A_i)] = \mu(A_1) - \mu[\cup_{i=1}^\infty (A_1 - A_n)] = \mu(A_1) - \lim_{n \rightarrow \infty} \mu(A_1 - A_n) = \mu(A_1) - \lim_{n \rightarrow \infty} [\mu(A_1) - \mu(A_n)] = \lim_{n \rightarrow \infty} \mu(A_n)$$

Section 2 answers**Ex 2.10**

We know that since μ^* is an outer-measure, it is countably subadditive. i.e. $\mu^*(\cup_i^\infty A_i) \leq \Sigma_i \mu^*(A_i)$ To prove the statement we can show that the \geq in Theorem 2.8 can be replaced by a \leq .

Rewriting the statement regarding countable subadditivity gives: $\mu^*(\cup\{B \cap E, B \cap E^c\}) \leq \mu^*(B \cap E) + \mu^*(B \cap E^c)$ By the definition of B we can say that the left hand side equals $\mu^*(B)$ Thus we have shown that the \geq in Theorem 2.8 can be replaced by a \leq and the proposition is proved.

Ex 2.14

We define \mathcal{O} as all the open sets in \mathbb{R} . Define ν as the premeasure on \mathbb{R} . μ^* is the outer measure on \mathbb{R} generated by ν . Denote $\sigma(\mathcal{O})$ as the σ -algebra generated by \mathcal{O} . Then we can use Theorem 2.12, to say that $\sigma(\mathcal{O})$ is contained within the σ -algebra generated by the Caratheodory construction. Since $\sigma(\mathcal{O})$ is the σ -algebra generated by \mathcal{O} , it is the Borel sigma field, so we have proved the statement.

Section 3 answers**Ex 3.1**

The subset we want the measure of is countable, so let us define it as $X = \{x_1, x_2, \dots\}$ where x_i are subsets of the real line.

Then let us define a cover of this set:

$$Cover = \{x_i - \frac{\epsilon}{2^i}, x_i + \frac{\epsilon}{2^i}\}$$

The total length of this cover (by taking an infinite sum) is 2ϵ

Therefore we can pick ϵ low enough such that the measure of X is zero.

Ex 3.4

We want to explain how $\{x \in X : f(x) < a\}$ can be replaced by any of three other conditions: 1. $\{x \in X : f(x) \leq a\}$ 2. $\{x \in X : f(x) > a\}$ 3. $\{x \in X : f(x) \geq a\}$

Proving 3: M is the σ -algebra generated by X . Since σ -algebra's are closed under complements, then if the sets such that $f(x) < a$ are in M , then the sets such that $f(x) \geq a$ must also be in M . Thus we can replace the original condition by condition 3.

Proving 2: Lets create a sequence $\{a_n\}$ where the limit is a . We know that $A_n = \{x \in X : f(x) \geq a_n\}$ is in M from the above proof. We also know that M is closed under countable unions, and since all A_n are in M , we can write: $\cup_i^\infty A_n \in M$. And since a is the limit of the sequence $\{a_n\}$, we can also write this as $\{x \in X : f(x) > a\}$.

Proving 1: Using the same argument we used for 3, on 2, we can prove 1.

Ex 3.7

$f + g$ and $f * g$ are both continuous functions, therefore property 4 implies that they are measurable functions. If a maximum exists for (f, g) then it is the supremum (and vice versa for the infimum), therefore property 2 implies that $\max(f, g)$ and $\min(f, g)$ are measurable. Finally $|f|$ can be rewritten as the continuous function: $F = (f(x)^2)^{0.5}$ thus we can use property 4 to prove this is also measurable.

Section 4 answers

(worked with Cache and Alberto on these answers)

Exercise 4.13:

Since $0 \leq \|f\| < M$, we can apply Proposition 4.5 to obtain $0 \leq \int_E \|f\| d\mu \leq M\mu(E) < \infty$. Therefore $f \in \mathcal{L}^1(\mu, E)$.

Exercise 4.14:

Proof by contrapositive. Suppose there exists a measurable set $E' \subset E$ with positive μ -measure such that $f(E') = \{\infty\}$ (we consider just ∞ without loss of generality). Then $\infty = \int_{E'} f d\mu \leq \int_E f d\mu \leq \int_E \|f\| d\mu$ (the proof of the first inequality can be found in the proof of Exercise 4.16). Therefore f is not in $\mathcal{L}^1(\mu, E)$.

Exercise 4.15:

Define $B(f) := \{s : 0 \leq s \leq f, s \text{ measurable and simple}\}$. Since $f \leq g$, $f^+ \leq g^+$ and $f^- \geq g^-$. Then $B(f^+) \subset B(g^+)$, which implies that $\int_E f^+ d\mu \leq \int_E g^+ d\mu$, and $B(g^-) \subset B(f^-)$, which implies that $\int_E f^- d\mu \geq \int_E g^- d\mu$. Therefore

$$\int_E f d\mu = \int_E f^+ d\mu - \int_E f^- d\mu \leq \int_E g^+ d\mu - \int_E g^- d\mu = \int_E g d\mu.$$

Exercise 4.16:

Fix an arbitrary measurable simple function $s(x) := \sum_{i=1}^N c_i \chi_{E_i}$ (definition from the lecture notes). Since $A \subset E$, $\mu(A \cap E_i) \leq \mu(E \cap E_i)$ for each i . Then $\int_E s d\mu := \sum_{i=1}^N c_i \mu(A \cap E_i) \leq \sum_{i=1}^N c_i \mu(E \cap E_i) = \int_A s d\mu$. Since the choice of s was arbitrary,

$$\int_A \|f\| d\mu = \sup \left\{ \int_A s d\mu : 0 \leq s \leq \|f\|, s \text{ simple, } s \text{ measurable} \right\}$$

is less than or equal to

$$\int_E \|f\| d\mu = \sup \left\{ \int_E s d\mu : 0 \leq s \leq \|f\|, s \text{ simple, } s \text{ measurable} \right\}.$$

Exercise 4.21:

Define $\lambda_1(A) := \int_A f^+ d\mu$ and $\lambda_2(A) := \int_A f^- d\mu$, then $\int_A f d\mu = \lambda_1(A) - \lambda_2(A)$. Since $A = (A - B) \cup B$ and λ_i is a measure for $i = 1, 2$ (Theorem 4.6), $\lambda_i(A) = \lambda_i(A - B) + \lambda_i(B)$ for $i = 1, 2$. However, by Proposition 4.6 we have $\lambda_i(A - B) = 0$ for $i = 1, 2$. Therefore, $\lambda_i(A) = \lambda_i(B)$ for $i = 1, 2$. This implies that $\int_A f d\mu = \lambda_1(B) - \lambda_2(B) = \int_B f d\mu$, which implies the result of the corollary.
